## $\leftarrow$

## **Practice Quiz: Advanced Regular Expressions**

TOTAL POINTS 5

1. We're working with a CSV file, which contains employee information. Each record has a name field, followed by a phone number field, and a role field. The phone number field contains U.S. phone numbers, and needs to be modified to the international format, with "+1-" in front of the phone number. Fill in the regular expression, using groups, to use the transform\_record function to do that.

1 point

```
def transform_record(record):
           new\_record = re.sub(r"\b(\d{3}-\d{3}-?\d{4})\b",r"+1-\l",record)
           return new_record
        print(transform_record("Sabrina Green,802-867-5309,System Administrator"))
# Sabrina Green,+1-802-867-5309,System Administrator
         print(transform_record("Eli Jones,684-3481127,IT specialist"))
         # Eli Jones.+1-684-3481127.IT specialist
         print(transform_record("Melody Daniels,846-687-7436,Programmer"))
   13
         # Melody Daniels,+1-846-687-7436,Programmer
   14
   15
         print(transform_record("Charlie Rivera,698-746-3357,Web Developer
         # Charlie Rivera,+1-698-746-3357,Web Developer
Sabrina Green, +1-802-867-5309, System Administrator
Eli Jones,+1-684-3481127,IT specialist
Melody Daniels,+1-846-687-7436,Programmer
Charlie Rivera, +1-698-746-3357, Web Developer
```

The multi\_vowel\_words function returns all words with 3 or more consecutive vowels (a, e, i, o, u). Fill in the regular expression to do that. 1 point

```
def multi_vowel_words(text):
         pattern = r'\b\w*[aeiou]{3,}\w*\b'
          result = re.findall(pattern, text)
         return result
       print(multi_vowel_words("Life is beautiful"))
       # ['beautiful']
       print(multi_vowel_words("Obviously, the queen is courageous and gracious."))
       # ['Obviously', 'queen', 'courageous', 'gracious']
       print(multi_vowel_words("The rambunctious children had to sit quietly and aw
  13
       # ['rambunctious', 'quietly', 'delicious']
       print(multi_vowel_words("The order of a data queue is First In First Out (FI
  16
  17
       # ['queue']
       print(multi_vowel_words("Hello world!"))
  19
  20
['beautiful']
['Obviously', 'queen', 'courageous', 'gracious']
'rambunctious', 'quietly', 'delicious']
['queue']
```

3. When capturing regex groups, what datatype does the groups method return?

1 point

A string

A tuple

O A list

O A float

4. The transform\_comments function converts comments in a Python script into those usable by a C compiler. This means looking for text that begins with a hash mark (#) and replacing it with double slashes (//), which is the C single-line comment indicator. For the purpose of this exercise, we'll ignore the possibility of a hash mark embedded inside of a Python command, and assume that it's only used to indicate a comment. We also want to treat repetitive hash marks (##), (###), etc., as a single comment indicator, to be replaced with just (//) and not (#//) or (//#). Fill in the parameters of the substitution method to complete this function:

```
import re
def transform_comments(line_of_code):
    result = re.sub("#{1,}", "//", line_of_code)
    return result

print(transform_comments("### Start of program"))
# Should be "// Start of program"
print(transform_comments(" number = 0 ## Initialize the variable"))
# Should be " number = 0 // Initialize the variable"
print(transform_comments(" number += 1 # Increment the variable"))
```

```
11 # Should be " number += 1 // Increment the variable"
12 print(transform_comments(" return(number)"))
13 # Should be " return(number)"

Reset

// Start of program
number = 0 // Initialize the variable
number += 1 // Increment the variable
return(number)
```

5. The convert\_phone\_number function checks for a U.S. phone number format: XXX-XXXX (3 digits followed by a dash, 3 more digits followed by a dash, and 4 digits), and converts it to a more formal format that looks like this: (XXX) XXX-XXXX. Fill in the regular expression to complete this function.

```
import re
def convert_phone_number(phone):
    result = re.sub(r'(\d{3})-(\d{4})\b', r'(\l) \2-\3', phone)
    result = re.sub(r'(\d{3})-(\d{4})\b', r'(\l) \2-\3', phone)
    return result

print(convert_phone_number("My number is 212-345-9999.")) # My number is (21 print(convert_phone_number("Please call 888-555-1234")) # Please calleu(888)
print(convert_phone_number("123-123-12345")) # 123-123-12345
print(convert_phone_number("Phone number of Buckingham Palace is +44<sup>Rog</sup>65 123

My number is (212) 345-9999.
Please call (888) 555-1234
123-123-12345
Phone number of Buckingham Palace is +44 303 123 7300
```
